Abstract

Zinc deficiency is the most widespread micronutrient disorder in the production of wheat (*Triticum aestivum* L.) and other cereal crops. An experiment was conducted in greenhouse, in 2013, using the sterile sand-perlite (2:1 v/v), to study the effects of two beneficial microorganisms on growth and nutritional status of wheat (Nicknejad cultivar). The study was arranged as factorial in a completely randomized design with three replications. The experimental factors consisted of *Piriformospora indica* (E_0: Uninoculated; E_1: Inoculated), *Pseudomonas putida* (E_0: Uninoculated; E_1: Inoculated) and Zinc (Zn_0: 0; Zn_1: 2µM $ZnSO_4$). The results showed that inoculation by *P. putida* increased shoot dry weight at both levels of zinc, but this increase was observed for root dry weight only without zinc application. The iron concentration of shoot was decreased as a result of inoculation by *P. putida* at both levels of zinc. However, *P. indica* inoculation increased iron concentration in zinc application, but had no significant effect without zinc application. At both levels of zinc, the highest P, Zn, chlorophyll a and b concentrations were achieved by inoculation with *P. indica*. Inoculation by *P. putida* reduced P concentration at both levels of zinc but it reduced Zn, chlorophyll a and b concentrations only with zinc application. The results of this research showed that despite negative effect of *P. putida* on nutrient uptake, inoculation by *P. putida* and/or *P. indica* plays an important role in the promotion of wheat growth in zinc deficiency conditions.
